GPA Rotation for Factor Analysis

Description

Index

GPArotation implements Gradient Projection Algorithms and several rotation objective functions for factor analysis.

13

Details

2 GPA

Package: GPArotation
Depends: R (>= 2.0.0)
License: GPL Version 2.

URL: http://www.stat.ucla.edu/research or

http://www.stat.ucla.edu/research/gpa

The main optimization functions are GPForth and GPFoblq. Rotation objectives include oblimin and many others.

Author(s)

Coen A. Bernaards and Robert I. Jennrich with some R modifications by Paul Gilbert.

Code is modified from original source 'splusfunctions.net' available at http://www.stat.ucla.edu/research/gpa.

GPA

Rotation Optimization

Description

Gradient projection rotation optimization routine used by various rotation objective.

Usage

```
GPForth(A, Tmat=diag(ncol(A)), normalize=FALSE, eps=1e-5, maxit=1000,
   method="varimax", methodArgs=NULL)
GPFoblq(A, Tmat=diag(ncol(A)), normalize=FALSE, eps=1e-5, maxit=1000,
   method="quartimin", methodArgs=NULL)
```

GPA 3

Arguments

A initial factor loadings matrix for which the rotation criterian is to be optimized.

Tmat initial rotation matrix.

method rotation objective criterian.

normalize see details.

eps convergence is assumed when the norm of the gradient is smaller than eps.

maxit maximum number of iterations allowed in the main loop.

methodArgs a list ofmethodArgs arguments passed to the rotation objective

Details

Gradient projection rotation optimization routines developed by Coen A. Bernaards and Robert I. Jennrich. These functions can be used directly to rotate a loadings matrix, or indirectly through a rotation objective passed to a factor estimation routine such as factanal. For examples of the indirect use see the documention for rotations (such as oblimin).

GPForth is the main GP algorithm for orthogonal rotation. GPFoblq is the main GP algorithm for oblique rotation. Both algorithms require a loadings matrix A which fixes the equivalence class over which the optimization is done. It must be the solution to the orthogonal factor analysis problem. A rotation is defined as codeA %*% t(solve(Tmat)). For the orthogonal case Tmat is orthonormal so this simplifies to codeA %*% Tmat. The starting point for iterative optimization is given by the Tmat rotation of A. By default the initial rotation is the identity matrix. For some rotation criteria local optima may exist and it is recommended to check for this by starting with many different initial rotations. The function Random. Start will help to do this.

The argument method can be used to specify a string indicating the rotation objective. GPFoblq defaults to "quartimin" and GPForth defaults to "varimax". Available rotation objectives are "oblimin", "quartimin", "target", "pst", "oblimax", "entropy", "quartimax", "varimax", "simplimax", "bentler", "tandemI", "tandemII", "geomin", "cf", "infomax" and "mccammon". The string is prefixed with "vgQ." to give the actual function call. The vgQ.* function call would typically not be used directly, so these methods are not exported from the package namespace. You can print these functions to see the code for calculating a criterion, but since they are not exported the package name needs to be specified. For example, use GPArotation::vgQ.oblimin to view the function vgQ.oblimin.

Some rotation criteria (including "simplimax", "pst", "procrustes") require one or more additional arguments. For example, "simplimax" needs the number of 'close to zero loadings' which is given as the extra argument k. Check the rotation methods for details. (If a new rotation method is implemented and needs additional arguments then this is the way to pass them.)

The argument normalize gives an indication of if and how any normalization should be done before rotation, and then undone after rotation. If normalize is FALSE (the default) no normalization is done. If normalize is TRUE then Kaiser normalization is done. (So squared row entries of normalized A sum to 1.0.) If normalize is a vector of length equal to the number of indicators (= number of rows of A) then the colums are divided by normalize before rotation and multiplied by normalize after rotation. If normalize is a function then it should take A as an argument and return a vector which is used like the vector above.

Value

A GPArotation object which is a list with elements

Lh The rotated loadings, one column for each factor.

4 GPA

Th The rotation matrix, Lh %*% t(Th) = A.

Table A matrix recording the iterations of the rotation optimization.

method A string indicating the rotation objective function.
orthogonal A logical indicating if the rotation is orthogonal.
convergence A logical indicating if convergence was obtained.

Phi t(Th) %*% Th. The covariance matrix of the rotated factors. This will be the

identity matrix for orthogonal rotations so is omitted from the result of GPForth.

Examples

Harman 5

Harman

Example Data from Harman

Description

Harman8 is initial factor loading matrix for Harman's 8 physical variables.

Usage

data(Harman)

Format

The object Harman8 is a matrix.

Details

The object Harman8 is loaded from the data file Harman.

Source

Harman, H. H. (1976) Modern Factor Analysis, Third Edition Revised, University of Chicago Press.

See Also

GPForth, Thurstone, WansbeekMeijer

Normalizing Weight Internal Utility for Normalizing Weights

Description

See GPFobliq and GPForth.

Usage

NormalizingWeight(A, normalize=FALSE)

Arguments

A loading matrix.

 ${\tt normalize} \qquad {\tt An indication of if/how the matrix should be normalized}.$

Value

A matrix.

6 Random.Start

Random.Start

Generate a Random Orthogonal Rotation

Description

Random orthogonal rotation to use as Tmat matrix to start GPForth or GPFoblq.

Usage

```
Random.Start(k)
```

Arguments

k

An integer indicating the dimension of the square matrix.

Details

The random start function produces an orthogonal matrix with columns of length one based on the QR decompostion.

Value

An orthogonal matrix.

   }

data("Thurstone", package="GPArotation")</pre>
```

Thurstone 7

```
Global.min(box26, "simplimax",10)
```

Thurstone

Example Data from Thurstone

Description

box20 and box26 are initial factor loading matrices.

Usage

data(Thurstone)

Format

The objects box20 and box26 are matrices.

Details

The objects box20 and box26 are loaded from the data file Thurstone.

```
print.GPArotation Print and Summary Methods for GPArotation
```

Description

Print an object or summary of an object returned by GPForth or GPFoblq.

Usage

```
## S3 method for class 'GPArotation':
print(x, digits=3, Table=FALSE, ...)
## S3 method for class 'GPArotation':
summary(object, ...)
## S3 method for class 'summary.GPArotation':
print(x, digits=3, ...)
```

Arguments

```
object a GPArotation object to summarize.

x a summary.GPArotation to print.

digits precision of printed numbers.

... further arguments passed to other methods.
```

Value

The object printed or a summary object.

See Also

```
GPForth, summary
```

rotations Rotations

Description

Optimize factor loading rotation objective.

Usage

```
oblimin(L, Tmat=diag(ncol(L)), gam=0, normalize=FALSE, eps=1e-5, maxit=1000)
quartimin(L, Tmat=diag(ncol(L)), normalize=FALSE, eps=1e-5, maxit=1000)

vgQ.tandemI(L)
vgQ.tandemII(L)
vgQ.geomin(L, delta=.01)
vgQ.cf(L, kappa=0)
vgQ.infomax(L)
vgQ.mccammon(L)
```

Arguments

L a factor loading matrix

Tmat initial rotation matrix.

gam 0=Quartimin, .5=Biquartimin, 1=Covarimin.

Target rotation target for objective calculation.

W weighting of each element in target.

k number of close to zero loadings.

delta constant added to L2 in objective calculation.

kappa see details.

normalize parameter passed to optimization routine (GPForth or GPFoblq).

eps parameter passed to optimization routine (GPForth or GPFoblq).

maxit parameter passed to optimization routine (GPForth or GPFoblq).

Details

These functions optimize a rotation objective. They can be used directly or the function name can be passed to factor analysis functions like factanal. Several of the function names end in T or Q, which indicates if they are orthogonal or oblique rotations (called from GPForth or GPFoblq respectively.

The vgQ.* versions of the code are called by the optimization routine and would typically not be used directly, so these methods are not exported from the package namespace. (They simply return the function value and gradient for a given rotation matrix.) You can print these functions but the package name needs to be specified, since they are not exported. For example, use GPArotation:::vgQ.oblimin to view the function vgQ.oblimin. The T or Q ending on function names should be omitted for the vgQ.* versions of the code so, for example, use GPArotation:::vgQ.target to view the target criterion calculation.

oblimin family

Rotations which are available are

oblique

oblimin

oblimin	oblique	oblimin family
quartimin	oblique	
targetT	orthogonal	target rotation
targetQ	oblique	target rotation
pstT	orthogonal	partially specified target rotation
pstQ	oblique	partially specified target rotation
oblimax	oblique	
entropy	orthogonal	minimum entropy
quartimax	orthogonal	
varimax	orthogonal	
simplimax	oblique	
bentlerT	orthogonal	Bentler's invariant pattern simplicity criterion
bentlerQ	oblique	Bentler's invariant pattern simplicity criterion
tandemI	orthogonal	Tandem Criterion
tandemII	orthogonal	Tandem Criterion
geominT	orthogonal	
geominQ	oblique	
cfT	orthogonal	Crawford-Ferguson family
cfQ	oblique	Crawford-Ferguson family
infomaxT	orthogonal	
infomaxQ	oblique	
mccammon	orthogonal	McCammon minimum entropy ratio

Note that Varimax defined here uses vgQ.varimax and is not varimax defined in the stats package. stats:::varimax does Kaiser normalization by default whereas Varimax defined here does not.

The argument kappa parameterizes the family for the Crawford-Ferguson method. If m is the number of factors and p is the number of indicators then kappa values having special names are 0=Quartimax, 1/p=Varimax, m/(2*p)=Equamax, m-1/(p+m-2)=Parsimax, m-1/(p+m-2

New rotation methods can be programmed with a name "vgQ.newmethod". The inputs are the matrix L, and optionally any additional arguments. The output should be a list with elements

f the value of the criterion at L.

Gq the gradient at L.

Method a string indicating the criterion.

Value

A list as needed by factanal with elements

Lh from GPForth or GPFoblq.Th Th from GPForth or GPFoblq.Table Table from GPForth or GPFoblq.

logical Convergence indicator from GPForth or GPFoblg.
